ABSTRACT

Four major types of forest vegetation viz., moist sal forest, moist mixed forest, dry mixed forest and seral vegetation were identified at the Kanha National Park using remote sensing data products viz., satellite imageries (Landsat - TM - FCC 1:50,000 scale) and aerial photographs (B/W panchromatic 1:10,000 scale). Primary analysis of the vegetation has revealed that sal (*Shorea robusta*) was more abundant (60.13) with highest importance value index (IVI) of 180.11 followed by *Terminalia tomentosa* in moist sal group of forests in valleys. *T. tomentosa* was found to be a close associate of sal. In moist mixed forests (on hill slopes), *T. tomentosa* were abundant with high frequency, density and highest IVI (94.88). Total absence of sal and less abundance of *T. tomentosa* were the significant aspects in characterizing the dry mixed forest. In dry mixed forest, *Boswellia serrata* and *Lagerstroemia parviflora* are the most abundant species constituting the ridge vegetation. The seral vegetation was dominated by *Butea monosperma* and *L. parviflora* which were invading the grasslands in pure patches, respectively, into meadows and dadar grasslands.

KEY WORDS : Remote sensing, ecosystem, environment, vegetation analysis, phytosociology, satellite imageries, aerial photographs

Vegetation analysis is paramount importance in understanding about our forest ecosystem and their environment. The various components of forest ecosystem interacts either directly or indirectly, in such a way that all the components together perform some system function. Forest fire, illegal felling or large scale deforestation in tropical forest area will certainly affect our forest ecosystem. Because of these unexpected biotic and abiotic events the phytosociological settings of natural forest ecosystem gets disturbed. Primary analysis of forest vegetation aims at quantitative description of phytosociology and ecology of plant communities. This is not an easy job if we go for conventional methods of vegetation analysis considering the vastness and inaccessibility of tropical forest environment. This becomes an uphill task especially if we want to have vegetation analysis of particular forest ecosystem at very frequent intervals. In the light of these conditions, remote sensing as a tool for vegetation analysis had gained momentum only a decade back by virtue of its synoptic coverage of vast terrain and repeatability (Roy, 1983). The present study was undertaken to delineate the different types of forest as well as to have primary analysis of forest vegetation using remote sensing technique.

MATERIALS AND METHODS

The study area comprised part of the Kanna National Park (80° 26' to 80° 30' E longitude and 22° 07' to 22° 22' N latitude). Remote sensing data products viz., satellite imageries and aerial photographs pertaining to the study area were obtained from the National Remote Sensing Agency (NRSA), Hyderabad. The boundary of the study area was marked using survey of India toposheets (1:50,000 scale). The satellite imageries (Landsat -TM - FCC 1:50,000 scale) were used to identify visually the broad physiognomic units of forest vegetation as it was unable to give 3-D view of the objects in the study area. Whereas the aerial photographs (B/W panchromatic 1 : 10,000 scale) were used to identify specific vegetation or forest types (Champion and Seth, 1968) within each of the broader physiognomic units identified on satellite imageries. Informations such as stand height, crown diameter, crown density, slope of the terrain, topstorey and understorey vegetation etc., of the study area were also obtained through aerial photographs in view of its 3-D effect. 31 sample plots were marked on aerial photographs for various forest types following proportional stratified random sampling technique. These sample plots were located on the ground (study

area) for collecting ground truth besides checking for the correctness of the already interpreted / identified details on aerial photographs and satellite imageries. Ground truth was collected from sample plots of 0.1 ha in the field (forest area).

Data on number of tree species, tree height, diameter at breast height (DBH), basal area, topstorey and understorey species etc., were collected from a quadrat of 10 m x 10 m in each sample plot in the field. The whole spectrum of work was done systematically in three phases viz., pre-field, field and postfield work (Kuchlex, 1967). Primary analysis of vegetation interms of abundance, density, frequency, basal area, relative frequency

(RF), relative density (RD), relative basal area (RBA) and importance value index (IVI) were done using the sample plot data following the procedures adopted by Phillips (1959). The abundance/frequency ratio (Ab/F) suggested by Whitford (1948) as a measure of contagiousness or dispersion was also worked out.

RESULTS AND DISCUSSION

Four major types of vegetations viz., sal forest, moist mixed forest, dry mixed forest and seral vegetation were identified in the study area from the remote sensing data products viz., satellite imageries and aerial photographs based on the physiognomical variations. The primary analysis

RF = Relative frequency; RD = Relative density; RBA = Relative basal area; IVI = Importance value index; Ab = Abundance; F = Frequency

pertaining to these vegetations are furnished in Tables 1 to 4.

Sal forest

The sal was more abundant (60.13) followed by *Ougenia* (6.67), *Terminalia* (5.6) and *Lagerstroemia* (4.0). The frequency of sal was highest (100%) followed by *Terminalia* (75%) *Anogeissus* and *Ghirri* (50%), *Ougenia*, *Diospyros*, *Embllica*, *padar* and *Kumbhi* (37.5%). The IVI of the sal was the highest (180.11) followed by *Terminalia* (17.04) and *Ougenia* (10.22).

The top canopy was constituted by Sal, *Terminalia* and Jamun. But *Terminalia* was observed as very close associate of sal which was evident from the abundance, frequency, and IVI of *Terminalia*. Though Jamun was observed in the top canopy, it was not frequent as that of *Terminalia* which was confirmed by less abundance (2.0), low frequency (12.5), very low IVI (2.21) and irregular dispersion of Jamun (Ab/F ratio was 0.16)

The first storey was constituted by some prominent species viz., *Anogeissus*, *Ghirri*, *Ougenia*, *Diospyros*, *Stereospermum*, *Embllica*, *Kumbhi*, *Lagerstroemia* etc., besides other

miscellaneous species (Table 1). Bamboo, grass, shrubs, seedlings of Sal, *Terminalia*, *Diospyros*, *Lagerstroemia* etc., forms ground storey.

Moist mixed forest

The top canopy was constituted by *Terminalia*, Sal, *Diospyros*, *Anogeissus* and *Bridelia retusa*. Among these species *Terminalia* was more abundant (21.14) with highest frequency (100 percent) and density (21.14) and ultimately

registered highest IVI (94.88), followed by Sal, *Diospyros*, *Anogeissus* and *Bridelia retusa*.

The first storey comprised of prominent species viz., *Lagerstroemia*, *Ougenia*, *Terminalia chebula*, *Bauhinia retusa* and *Emblia* besides other miscellaneous species (Table 2). Bamboo, grass, shrubs, seedlings of prominent species etc., occurred as groundstorey.

RF = Relative frequency; RD = Relative density; RBA = Relative basal area; IVI = Importance value index; Ab = Abundance; F = Frequency

Dry mixed forest

The top canopy was formed by *Terminalia*, *Bosewellia*, *Lagerstroemia* and *Anogeissus*. The major change in floristic composition was absence of Sal and less abundance of *Terminalia* (5.6) as against 21.14 in the moist mixed forest, though the frequency of *Terminalia* was 83.33 per cent. The significant change in the composition of species was due to the abundance of *Bosewellia* and *Lagerstroemia* which are characteristics of ridge vegetations.

The first storey was constituted by prominent species like *Buchnanania*, *Diospyros*, *Gabi*, *Embllica* and *Ghatta* besides other miscellaneous species (Table 3). Bamboo and grasses occurred as ground storey.

Seral vegetation

This group of vegetation was dominated by *Butea monosperma* and *Lagerstroemia* invading the grasslands in pure patches, respectively, on meadow were dadar grasslands. Occasionally *Ougeinia* and *Terminalia* were found to invade grasslands on dadars besides *Lagerstroemia*. On meadow grasslands Sal was found occasionally intruding besides *Butea*. The understory was

mostly grasses. The other species which occur sparsely in seral formations were Majini, Lasrey, *Embllica*, *Bauhinia racemosa*, *Terminalia chebula*, *Bauhinia malabaricum* and *Zizyphus xylophora* (Table 4).

It is concluded that remote sensing can be used as a tool to do vegetation analysis with adequate ground truth. The integrated use of both aerial photograph and satellite imageries is very essential to accomplish the task.
