REVIEW

RICE PEST COMPLEX : AN APPRAISAL

K.GUNATHILAGARAJ and M.GANESH KUMAR

Department of Environmental Sciences
 Agricultural College and Research Institute
 Tamil Nadu Agricultural University
 Coimbatore 641 003

More than 800 insect species are reported to damage rice crop in varying degrees and only 20 are of major importance and regular occurrence (Grist and Lever, 1969). Occurrence of a large number of insect pests has been cited often as a major bottle-neck in achieving higher yield in rice similar to that, which occurred in wheat following the introduction of high yielding varieties (Pradhan, 1971). Based on the published data, we are able to list 537 organisms on rice, which include 385 insects (Table 1), 51 nematodes, 15 mites, 5 earthworms, 7 snails, 2 tadpole shrimps, 1 eel fish, 9 crabs, 3 large mammals, 4 rodents and 54 birds (Table 2) in our country. Yield loss due to the pests alone was put at 31.5 per cent in Asia (Cramer, 1967). The loss is expected to be much more in endemic areas, as in Maruteru where only 625 kg/ha yield was obtained without any protection as compared to 4504 kg/ha with protection (AICRIP, 1972), suggesting a loss of about 86 per cent.

CHANGING STATUS OF PESTS

During the last two decades, the insect pest complex of the rice crop has undergone a tremendous change (Pathak and Dhaliwal, 1980). Species like leaf folders, whorl maggots, thrips, caseworms, armyworms and cutworms that were minor pests earlier have started appearing in epidemic forms, whereas the incidence of a few like stemborers and rice hispa has declined somewhat (Table 3). Certain insect species that were known to attack rice during a particular crop season only have started occurring throughout the

year (gall midge) while others have expanded the areas of their occurrence. This has given rise to new pest problems in several areas.

The brown planthopper (BPH), *Nilaparvata lugens* (Stal.), a minor pest till mid 1960 has become a major threat since 1970s, causing severe damage in several states of our country (Dyck and Thomas, 1979). Of the various changes in production practices, the increased use of resurgence inducing insecticides has been considered as the major cause of intensified BPH problems in India. The whitebacked planthopper, (WBPH), *Sogatella furcifera* (Horvath), is slowly becoming a major pest in major rice growing tracts, especially in Madhya Pradesh and Punjab (Mochida, 1982). Since 1964, the green leadhopper (GLH), *Nephotettix* spp., has become a chronic pest of rice (Kulshreshtha *et al.* 1970 ; Ling, 1976). The rice gall midge, *Orseolia oryzae* (Wood- Mason) is also spreading its area of occurrence in the country. Even though first reported in neighbouring Bihar in 1880, it was recorded for the first time in 1971 only in Uttar Pradesh (Chaturvedi, 1971) and has become a regular pest since then (Rizvi and Singh, 1980). It was abundant during the wet season only but in the recent years, large infestations have been recorded in the dry season crop also (Kalode, 1974 ; Kalode and Kasi Viswanathan, 1976 ; Panda, 1978). The gall midge has been conventionally a pest of low land irrigated rice, but it has started attacking deep water rice (Venugopala Rao, 1975) and hill rices

* From several sources including Jairajpuri and Baqri (1991) and Salim Ali and Dillon Ripley (1989).

(Muthuswami, 1988). Also normally gall midge infestation does not occur beyond panicle initiation stage of crop growth, but recently it has been found to attack the crop even at the flowering stage (Rajamani *et al.*, 1979). Until the 1960s, the stemborers especially *Scirpophaga incertulas* (Walker) were generally considered the most

serious pests of rice throughout India. However, even though still a serious pest, the damage by stemborers seems to have somewhat declined in recent years and is attributed to the introduction of high yielding varieties, at least in Punjab (Dhaliwal, 1980). Another reason postulated is that the larvae of stemborers aestivate in stubbles and

are destroyed by the dry season land preparation. for the change in the insect pest fauna in rice
Crop intensification has been suggested as a reason (Loevinsohn, 1985). Intensification involves (1) an

Table 4. Status of rice pests in different states (Chelliah *et al.*, 1989)

Pest	Intensity	Occurrence (States)
Major Pests		
Gall Midge	Severe Moderate to severe	Madhya Pradesh, Orissa Bihar, Karnataka, Kerala, Uttar Pradesh, West Bengal, Andhra Pradesh
Leaf folder	Moderate to severe Light to moderate	Andhra Pradesh, Kerala, Maharashtra, Punjab, Tamil Nadu Assam, Bihar, Gujarat, Haryana, Jammu and Kashmir, Karnataka, Madhya Pradesh, Orissa, Punjab, Uttar Pradesh, West Bengal
Brown planthopper	Moderate to severe Low to moderate	Andhra Pradesh, Karnataka, Kerala, Madhya Pradesh, Orissa, Tamil Nadu. Assam, Maharashtra, Rajasthan, Uttar Pradesh
Green leafhopper	Moderate to severe Low to moderate	Andhra Pradesh, Madhya Pradesh, Tamil Nadu. Assam, Bihar, Gujarat, Himachal Pradesh, Jammu and Kashmir, Uttar Pradesh, West Bengal.
Yellow stem borer	Severe Moderate to severe Low to moderate	Maharashtra Andhra Pradesh, Kerala, Madhya Pradesh, Orissa Assam, Bihar, Gujarat, Haryana, Himachal Pradesh, Jammu and Kashmir, Karnataka, Punjab, Tamil Nadu, Uttar Pradesh, West Bengal.
Minor Pests		
Whitebacked planthopper	Moderate to severe Light to Moderate	Madhya Pradesh, Punjab, Uttar Pradesh Bihar, Gujarat, Haryana, Himachal Pradesh, Orissa
Hispa	Moderate to severe Light to moderate	Assam, Himachal Pradesh, West Bengal Bihar, Gujarat, Haryana, Madhya Pradesh, Orissa, Punjab, Uttar Pradesh
Earhead bug	Light to moderate	Bihar, Gujarat, Haryana, Madhya Pradesh, Orissa, Tamil Nadu, Uttar Pradesh, West Bengal
Armyworm	Light to moderate	Bihar, Gujarat, Maharashtra, Punjab
Sporadic Pests		
Caseworm		Kerala, Orissa, Tamil Nadu
Cutworm		Uttar Pradesh
Grasshopper		Maharashtra
Thrips		Kerala, Tamil Nadu
Root weevil		Bihar

increase in the number of crops grown per year. (2) an increase in the use of agricultural chemicals (fertilizers and pesticides) (3) planting of varieties responsive to fertilizers and pesticides, and (4) increased plant densities.

In addition, there are new records of many insect and non-insect pests in several areas indicating the increasing severity of the pest problems. For example, the smaller brown planthopper, *Laodelphax striatellus* Fallen, which is a severe pest of rice in Japan and Korea, has also been recently recorded from India (Shukla, 1979). A few other examples of new pests include a planthopper, *Unkanodes sapporonus* (Misra, 1975) and an aphid, *Tetraneura radicola* (Rai, 1975). Several others viz., sugarcane pyrrilla (Sukhani, 1971), rusty plum aphid, *Carolinaia (Hysteroneura) setariae* (Garg and Sethi, 1976), painted bug, *Bagrada cruciferarum* Kirkaldy (Sandhu, 1975), hairy caterpillar, *Leonodra vittata* Wik. (Rai and Gavi Gowda, 1975), *Cryptoblabes gnidiella* (Sasmal and Kulshreshtha, 1985) and field cricket, *Euscyrtus concinnus* Hanu (Sasidharan Pillai and Saradamma, 1979), hitherto unknown to attack rice were recently recorded infesting rice in our country. The status of important rice pests in different rice growing states in India is presented in Table 4 (Chelliah *et al.*, 1939).

With the pest status of most of the rice associated organisms still uncertain, it is imperative on the part of the rice entomologists to concentrate on the insect diversity of the rice crop before rice is tampered with by the biotechnologists. It is futile for the entomologists to manipulate the rice crop with toxin genes and inhibitor genes without attempting to know the ecological niche of the organisms associated with it.

MORPHOLOGICAL, CULTURAL, PHYSIOLOGICAL AND NUTRITIONAL STUDIES OF NEW *Fusarium* WILT PATHOGEN OF BRINJAL

V.K. MANDHARE

Mahatma Phule Krishi Vidyapeeth
Agricultural Research Station
Niphad 422 303

ABSTRACT

A new species of *Fusarium* causing wilt on brinjal was identified as *F.oxysporum* f.sp. *melongenae* on the basis of morphological, cultural, physiological and nutritional studies. The fungus produces hyaline, septate, cottony white to pink mycelium. The macroconidia were oval, hyaline, mostly non-septate or with a single septa. The pathogen produces abundant pale brown chlamydo spores either singly or in chains. Richard's agar as well as potato dextrose agar medium was the basal medium for growth and sporulation of the fungus. It utilises glucose, sucrose, lactose, xylose, sorbital and dextrin as a carbon sources while potassium and ammonium nitrate as a nitrogen sources. The optimum temperature and pH for the growth of fungus was $28 \pm 1^\circ\text{C}$ and 5.7 respectively whereas the thermal death point for the fungus was 59 to 60°C .

KEY WORDS : *Fusarium*, wilt pathogen, brinjal

Brinjal (*Solanum melongena* L.) is one of the most important vegetable crops grown throughout India. Among various pathogens infecting brinjal, *Fusarium* wilt is a serious one. The various species of *Fusarium* infecting brinjal are *F.oxysporum* Schl. (Ganacharya and Wankar, 1976), *F.solani* (Fournet and Jacqua, 1978) and a recently identified *F.oxysporum* f.sp. *melongenae* in India (Mandhare et al. 1989). However, causal agent of wilt of brinjal was first reported in the Netherlands (Steekelenbug and Van, 1976). Though the morphological, cultural, physiological and nutritional aspects of these various species are known, there is no literature on newly identified

F.oxysporum f. sp. *melongenae*. It was, therefore, studied and presented herewith.

MATERIALS AND METHODS

Morphological studies

The *Fusarium* cultures used under study were obtained from single spore isolation. To determine size of conidia/chlamydo spores, one hundred spores were measured under high power (45 X) using micrometers.

Cultural studies

Culture media viz., potato dextrose agar, Richards' agar, Ashbys' agar, oat meal agar,
