Coimbatore 641 003

Rice planthoppers, the brown planthopper (BPH), *Nilaparvata lugens* (Stål.) and the white-backed planthopper (WBPH), *Sogatella recifera* (Horvath) (Delphacidae : Hemiptera) are considered as the 'Green Revolution' induced pests. Importance of resistant rice cultivars in the rice pest management programme was realised in 1967 for the BPH and in 1973 for WBPH (Heinrichs, 1988). In all rice growing countries, national breeding programmes are being implemented to evolve resistant rice varieties to the planthoppers. There has been a substantial progress in this area and a number of varieties resistant to BPH and WBPH are now available for commercial cultivation in our country (Table 1). A large number of resistant sources have been identified for the planthoppers (Table 2). The concept of team research in developing resistant varieties has now been well appreciated by the participating scientists and in releasing modern rice varieties, there is greater awareness in infusing resistance. This paper reviews the state of art of the host plant resistance works on BPH and WBPH in India.

Brown planthopper (BPH), *Nilaparvata lugens* (Stål.)

Distinct differences in levels of resistance to the BPH under greenhouse conditions were first observed at IRRI in 1963 (Pathak *et al.*, 1969). Hence, a systematic evaluation of the world collection of *Oryza sativa* began in 1967 and by 1986, 400 accessions out of 50,000 accessions screened, have been identified as having resistance to *N. lugens* (Rapusas and Heinrichs, 1987). Most of the resistant accessions are from India and Sri Lanka. In addition, 132 wild *Oryza* spp. accessions have been identified as resistant (Heinrichs, 1988). Breeding programmes for BPH resistance have been established in most of the Asian countries and numerous varieties have been released since that of IRRI 76 in 1973 (Heinrichs, 1994). In India, many

BPH resistant varieties, viz., Jyothi, Co 42, Parijat, Bharti, Shakti, Sonasali, PY3, Suraksha, Sagar-Samba, Chandan, Vajram, Prathiba, Chaitanya, Krishnaveni, Nandi, MTU 4870, Bhadra, Asha, Pavizham, Karthika, Aruna, Makam, Remya, Kanakam and Udaya have been released. But biotype selection in BPH has impeded the development of resistant varieties in many areas.

BPH resistance could not be traced to any morphological or anatomical characteristics of rice plants and is usually attributed to either a lack of phagostimulants or to the presence of antifeedants (Saxena, 1986). Low concentrations of amino acids, especially the sucking stimulant, asparagine, was considered to impart resistance to BPH in Mudgo (Sogawa and Pathak, 1970). Later, Yoshihara *et al.* (1979, 1980) reported that soluble silicic acid and oxalic acid in resistant rice plants served as sucking inhibitors. But this claim was disputed by the fact that both these acids are water soluble and their occurrence in phloem sap has not yet been demonstrated. Silica, which is the elemental form of the silicic acid and occurs in the soil, is more likely to be transported through the xylem vessels. On the other hand, oxalic acid, a product of plant's cellular metabolism, is highly toxic even to the plant tissues and therefore, less likely to occur in the phloem. Using a BPH resistant Japanese breeding line, Shigematsu *et al.* (1982) identified β-sitosterol and other sterols in the phloem sap. β-sitosterol is a strong BPH sucking inhibitor and Kaneda (1982) reported that low asparagine content intensifies the inhibitory effect of β sitosterol. Volatile chemicals (essential oils, terpenoids, aldehydes, fatty acids, esters, waxes, etc.) extracted as steam distillates have been shown to affect the behaviour and biology of the BPH (Saxena and Okech, 1985) even though the exact identity of allelochemicals is yet to be made.

Table 1. BPH resistant varieties released in India

Variety	Year of release	State	References
Suraksha (IET 7946)	1992	Andhra Pradesh	Prasada Rao <i>et al.</i> (1992)
PY3 (IR 13428-45-2)	1985	Podicherry	Bhagavndos <i>et al.</i> (1985)

Udaya (CR 190-103)	1985	Orissa	Misra <i>et al.</i> (1985)

Cook *et al.* (1987) suggested that the surface of the rice plant plays a role in food plant selection by the BPH. Surface waxes have been shown to affect BPH behaviour. Reduced settling and probing of the plant surface after the exploration and movement off of the stem on to the leaves results from chemical cues in the wax. Chemical cues received by the BPH from the plant surface originate from the alkanes or carbonyl compounds of the epicuticular wax and vary among cultivars. Analysis indicates that the chemical differences between waxes are due to a higher ratio of long to short carbon chain components in resistant cultivars. The enhanced surface activity and BPH dispersal from IR 46 (Woodhead and Padjham, 1988) may account for the field resistance of this cultivar (Heinrichs, 1986). The resistance mechanism is believed to be associated with minor genes which could be exploited in breeding for polygenic resistance to the BPH. Briefly, rice breeders have identified at least ten major genes conferring resistance to various populations of BPH. Resistance conferred by five genes, **Bph1**, **Bph3**, **Bph6**, **Bph9** and **Bph10** is inherited with dominance, whereas resistance conferred by the others, **bph2**, **bph4**, **bph5**, **bph7** and **bph8** is inherited recessively. **Bph1** and **bph2** are tightly interlinked, as are **Bph3** and **bph4**; therefore, no rice cultivar can be developed with both **Bph1** and **bph2** or **Bph3** and **bph4**. The other three genes, **bph5**, **Bph6** and **bph7** apparently segregate

independently of these two pairs (Kabir and Khush, 1988). Rice cultivars carrying **Bph1** gene (e.g., IR 26) were released starting in 1973, but field populations of BPHs adapted to these cultivars within three years. Cultivars containing the **bph2** gene (e.g., IR 36 and IR 42) were released starting in 1976 and gave effective BPH control for another six years. These were replaced by rice cultivars with the **Bph3** gene (e.g., IR 56 and IR 60) in 1982, but isolated cases of adaptation of BPH to **Bph3** gene have been found recently (Gallagher *et al.*, 1994). Thus field population of BPH have become successively virulent to resistance conferred by each of the first three major genes incorporated into agronomically accepted cultivars. Such virulent population of BPH have come to be known as biotypes. There are four biotypes of BPH known. Biotype 1 was prevalent in southeast and east Asia before the large scale cultivation of BPH-resistant varieties. Biotype 2 originated in 1976 in the Philippines, and biotype 3 was selected in the laboratory by rearing insects on resistant variety ASD 7. **Bph1** conveys resistance to biotypes 1 and 3 and **bph2** to biotypes 1 and 2, and **Bph3** and **bph4** convey resistance to all the three biotypes. Results of international nurseries indicated that varieties with **Bph1** or **bph2** were not resistant in southern Asia, hence biotype 4 was found in S Asia. ARC 10550, susceptible to the three biotypes in the Philippines, has a recessive gene for resistance to biotype 4. This gene was designated

bph5 and is independent of other four genes. Subsequent analysis revealed that the dominant gene of Swarnalata was designated Bph6. The recessive gene of T12 was designated bph7. The single recessive genes which are allelic to each other but are nonallelic to bph2 and bph4 were found in Col.5 Thailand and Col.11 Thailand and Chi-Saba. The recessive gene of these cultivars is nonallelic to bph5 and bph7 because bph5 and bph7 do not confer resistance to biotypes 1, 2 and 3 but the new gene does. Therefore, this recessive gene is different from all the other recessive genes and was designated bph8. Three varieties - Kaharamana, Balamawee and Pokkali - were found to have single dominant genes which are allelic to each other but are different from Bph1 and Bph3. This gene was designated as Bph9.

Several genes for resistance to the BPH have been transferred from wild *Oryza* species to

Table 3. Genes for resistance to *N. lugens* in rice and their reaction to different biotypes (Panda and Khush, 1995)

Gene	Chromo- some location	Reaction to indicated biotype

Bph 10 (t)	-	R	R	R	-

cultivated rice through wide hybridization (Jena and Khush, 1990). Genetic analysis to determine allelic relationships of these genes with known genes are underway. An introgression line from the cross of cultivated rice and *O. australiensis* has a dominant gene for BPH resistance which has been tentatively designated as Bph10 (t). It confers resistance to three biotypes. Thus on the basis of genetic analysis of about 90 varieties, 10 genes have been identified. The reaction of the known genes against four biotypes is shown in Table 3 (Panda and Khush, 1995).

The genes for resistance to BPH in rice varieties can be inferred without genetic analysis by determining their reaction to different biotypes. If a variety is resistant to biotypes 1 and 3, it is likely to have Bph1; if it is resistant to biotypes 1 and 2, it has bph2; and if it is resistant to all the three biotypes, it may have any of these - Bph3, bph4, bph8 and Bph9. Thus, varieties can be classified into varietal groups on the basis of their reaction to different biotypes before embarking on genetic analysis (Panda and Khush, 1995).

The concept of biotypes in BPH has been questioned on the grounds of stability of these biotypes and the usefulness of the term (Claridge and Den Hollander, 1980, 1983; Claridge *et al.*, 1984; Gallagher, 1988; Padgham *et al.*, 1989; Gallagher *et al.*, 1994).

Although minor morphometric differences among 'biotypes' have been identified (Saxena and Barrion, 1985), there is much overlap in

morphological characters, and after one generation of exposure to a susceptible variety, differences among 'biotypes' became smaller yet (Claridge *et al.*, 1984). Thus, morphological differences among biotypes may be a function of the selection regime imposed by laboratory rearing. Claridge and Den Hollander (1982) found ample variation for virulence with 'biotype' and after 10 generations of selection on different rice varieties, differences between 'biotypes' were greatly reduced. These results indicate that sufficient genetic variation exists for rapid adaptation and concomitant change in virulence to different rice varieties. In addition, biochemical evidence for BPH showed that the so-called 'biotypes' differed very little genetically and were no more different than the variants which exist in field populations (Den Hollander, 1989; Demayo *et al.*, 1990). Thus, BPH biotypes cannot be considered discrete genetic entities. Whereas certain 'biotypes' exhibit adaptation to particular host varieties compared to others, short periods of selection on novel varieties can alter their survival and performance. Results of Calridge and Den Hollander (1982), Gallagher (1988) and others, illustrate that there is not a one-to-one correspondence between a single gene in a BPH biotype and any single gene for resistance in the rice host.

Breeders and growers may be able to maximise the useful lifetimes of resistance genes by varying the direction and intensity of selection for adapted BPH genotypes by manipulating the crop's genetic structure in space and time. Several approaches have been proposed over the years such as rotating different cultivars, planting multiple resistant lines within the same field and combining different resistance genes within the same cultivar (Pathak and Khush, 1979; Khush, 1984; Heinrichs, 1986; Saxena and Khan, 1989). Each of these tactics may be useful, but the relative utility of each will be dependent on the genetic structure and mode of action of the virulence genes (i.e., the genes conferring adaptation to plant resistance genes) within the pest population.

Hybrids of rice varieties between *O. sativa* and other wild species viz. *O. latifolia*, *O. officinalis*, *O. eichengeri* and *O. ridleyi* were specifically produced to widen the gene pool of rice and

transfer useful alien genes to rice. Hybrids were produced between *O. sativa* and *O. ridleyi* by adopting embryo rescue technique to transfer yellow stem borer resistance to cultivated rice (IRRI, 1991). In the same manner, genes conferring resistance to BPH have been transferred to cultivated rice from its two wild relatives viz. *O. officinalis* (Jena and Khush, 1986) and *O. australiensis* (IRRI, 1991, 1993). The back crossing of hybrids derived between *O. sativa*/*O. latifolia* facilitated the transfer of BPH and whitebacked planthopper resistance genes from *O. latifolia* to *O. sativa*. All of the BPH resistant progenies were like the recurrent *O. sativa* parent in plant type, and did not carry any undesirable traits of *O. latifolia*. As many as 188 of the 2295 BC₃F₃ progenies tested were found to be resistant to WBPH (IRRI, 1993). Jena and Khush (1990) transferred resistance to BPH and WBPH to *O. sativa* breeding lines by crossing *O. officinalis*, a wild species with 2n=24 chromosomes and CC genomic constitution. A total of 400 F₁AC hybrids were obtained through the embryo rescue technique (Jena and Khush, 1986, 1989). These sterile AC hybrids between cultivated *O. sativa* and distant *O. officinalis* were backcrossed to *O. sativa*. Most of the BC₁ progenies were allotrioploid (AAC) and a few were hypotrioploid. AAC progenies were again backcrossed to *O. sativa*. BC₂ progenies consisting of disomics or aneuploids were identified in these progenies and were examined for the presence of *O. officinalis* chromosomes. Eleven different traits from *O. officinalis* were identified in these progenies including resistance to BPH and WBPH. Restricted recombinations were observed because of low pairing between A and C genomes. Because of this restricted recombination, the genotype of the recurrent parent was reconstituted after only two backcrosses.

The other example is the production of interspecific hybrids between *O. sativa* and *O. australiensis* (2n=24) with EE genome (Multani *et al.*, 1994). *O. australiensis* remains an important source for BPH resistance. Interspecific hybrids between three breeding lines of *O. sativa* and four accessions of *O. australiensis* were obtained after pollinating 20,234 spikelets of AE hybrids with t'

sativa pollen. To overcome this problem an autotetraploid of an elite breeding line (IR 31917-45-3-2) was induced and crossed with *O. australiensis*, to get F₁ hybrid plants (AAE) following embryo rescue. These triploids were backcrossed to *O. sativa*. The chromosome number of 16 BC₁ plants varied from 28 to 31, and all were male sterile. BC₂ plants had 24-28 chromosomes. Eight monosomic alien addition lines (MAALs) having a 2n chromosome complement of *O. sativa* and one chromosome of *O. australiensis* were selected from the BC₂F₂ progenies. BC₂ progenies consisting of disomic and aneuploid plants were examined for the presence of *O. australiensis* traits including BPH resistance. Resistance breeding programme for BPH may be expected to be a long term advantage only in combination with other control strategies, particularly biological control. In the absence of insecticide use, natural enemies of BPH generally maintain good levels of control. Effective pest management in tropical countries will depend on an integration of resistance breeding and biological control (Claridge, 1990).

Whitebacked planthopper (WBPH), *Sogatella furcifera* (Horvath)

The damage due to *S. furcifera* on rice crop has long been recorded but detailed studies on varietal resistance to WBPH have not been made until 1975 when research on host-plant resistance has been stepped up both at the IRRI and many Asian countries. The screening technique was perfected in 1967 (IRRI, 1967). Using the bulk seedling test, 48554 *O. sativa* accessions were screened and 401 (0.8 %) were selected resistant. They originated from 21 countries. Several species of wild rices were also identified as resistant to WBPH (Heinrichs *et al.*, 1985). Of the several IR varieties released, four varieties (IR 48, IR 52, IR 60 and IR 62) were found moderately resistant to WBPH (Heinrichs, 1986).

WBPH thrives on high-yielding, susceptible rice cultivars but fails to feed, grow, survive and reproduce adequately on resistant cultivars. No mechanical barriers to WBPH feeding have been identified in resistant plants. In resistant varieties, the mechanisms that operate against the pest are

antibiosis or a combination of both (Vaidya and Kalode, 1981; Gunathilagaraj and Chelliah, 1985; Saxena and Khan, 1989). Tolerance mechanism is associated with resistance in hybrid rices to WBPH (Nalini and Gunathilagaraj, 1995).

At least five genes have been identified that confer resistance to the WBPH. Four of them are dominant and designated as *Wbph 1*, *Wbph 2*, *Wbph 3* and *Wbph 5*. One is recessive and designated as *wbph 4* (Saxena and Khan, 1989). These five genes have been incorporated into improved germplasm at IRRI. WBPH resistant lines are being evaluated in coordinated trials. However, no resistant variety has yet been released (Khush and Chaudhary, 1981). Variety Pant Dhan 10 (IR 9763-11-2-2-3) is field resistant to WBPH in Uttar Pradesh and evaluated as IET 8616 in the All India Coordinated trials (Pandey *et al.*, 1994). ADT 38 (IR 21820-154-3-2-2-3) released in May 1987 for Tamil Nadu is also reported to be resistant to the WBPH (Sivasubramanian *et al.*, 1987) and HKR 120 (PtB 33/4* IR 3403-267-1) is a promising new rice resistant to WBPH in Haryana (Pal *et al.*, 1986).

In addition to major genes, minor genes also contribute to resistance against *S. furcifera* in some rice varieties and probably retard the selection of biotypes. Resistance has also been observed in wild rice species *viz.*, *Oryza eichingeri*, *O. latifolia*, *O. minuta*, *O. nivara*, *O. officinalis*, *O. paraguensis*, *O. punctata*, *O. ridleyi* and *O. rufipogon* (Heinrichs *et al.*, 1985). Because no modern variety is highly resistant to WBPH, attempts are being made to incorporate resistance genes into improved breeding lines. By wide crossing of cultivated rice and wild rice *O. officinalis* and through subsequent back crossing, breeding lines have been obtained which are highly resistant to WBPH.

It is interesting that none of the genes conferring resistance to any laboratory population of BPH also confer resistance to WBPH (Romema *et al.*, 1986). This suggests that different, largely independent factors govern resistance to each planthopper species. This obviously presents a problem to plant breeders desiring to develop cultivars resistant to both BPH and WBPH.

simultaneously. Nevertheless, the four released cultivars moderately resistant to WBPH (IR 48, IR 52, IR 60 and IR 62) also are resistant to atleast two of the three Philippine BPH laboratory populations (Heinrichs, 1986). Little is known at present about the potential abilities of WBPH to adapt to any of these resistant cultivars and the same cautious and research recommendations for the BPH are also applicable to the WBPH (Denno and Perfect, 1994).

Despite the availability of thousands of resistant sources for hoppers in India, host plant resistance studies have not made any significant impact on rice crop production in our country. It has only resulted in publication of a large number of 'research notes' without logical follow-up and conclusion. The reasons identified for the limited impact of host plant resistance in general (Teetes, 1985) are:

- ☆ failure of entomologists and plant breeders to complete their task after identifying the insect resistant germplasm
- ☆ failure of farmers to accept and use insect resistant cultivars
- ☆ the insecticide crutch
- ☆ tendency to separate crop production and crop protection, and
- ☆ failure to produce adequate information about the pest and the resistant cultivars.

EFFECT OF ETHREL AND CYCOCEL ON YIELD COMPONENTS OF CASSAVA

M. VIJAYAKUMAR and J.B.M.Md. ABDUL KHADER

Horticultural College and Research Institute
Tamil Nadu Agricultural University
Coimbatore 641 003

ABSTRACT

The effect of ethrel and cycocel each at three concentrations on the yield component of cassava varieties reveals that the total number of roots per plant was significantly influenced by CCC 5000 ppm and the same was more pronounced at the peak bulking phase. Among the varieties, Co.1 recorded a greater number of roots. The number of tuberous roots was more under the treatment ethrel 250 ppm and the variety Co.1 had the highest root number. The yield of tubers was significantly influenced by CCC, 10,000 ppm and the variety Co.1 recorded the highest yield.

KEY WORDS : Total number of roots, peak bulking, tuberous roots, yield components

A study of yield components in cassava could go a long way in increasing its productivity. Among the components, number of tubers, weight of tubers and girth of tubers are considered important. According to Jennings (1970), the number and size of tuber, the size and efficiency of the leaf canopy, the ratio of top/root and the duration of the period of dormancy are the yield components. Magooon *et al.* (1970) correlated the total yield with number of tubers per plant, tuber length, tuber circumference rind thickness and height of the plant. The storage root formation and development has been described in quantitative terms by many. Here an attempt was made to study the effect of growth substance on the yield components namely the number of total roots, tuberous roots and tuber yield.

MATERIALS AND METHODS

Studies were undertaken at the Horticultural College and Research Institute, Tamil Nadu Agricultural University, Coimbatore during 1983-86 with two varieties of cassava namely Co.1 and MVD.1 along with a promising culture

ME.116. Growth substance ethrel and CCC were applied each at three concentrations beginning from one month after planting at fortnightly intervals.

Main Plot Treatment

- T1 Ethrel 250 ppm
- T2 Ethrel 500 ppm
- T3 Ethrel 1000 ppm
- T4 CCC 2000 ppm
- T5 CCC 5000 ppm
- T6 CCC 10,000 ppm
- T7 Water spray
- T8 Control

Sub Plot

- V1. Co.1
- V2. ME 116
- V3. MVD.1
